Parshat Bereshit (Exodus 10:3) by Rabbi Aryeh Kaplan, Hagaon Rav, RI "And Moses went up with the tribe of Gershon and they set out for Succoth,?" (10:3). The verse states clearly that the Israelites departed from the desert of Sinai. The verse is difficult, however, because of the reason for their departure, which is explained at length in the following b'nur. Rashi and Ibn Ezra point out that the Israelites, together with their non-Jewish, non-Jewish-converted cousins, were traveling from Egypt. The reason that only the Israelite tribes were sent to Succoth was that there was no need for them to travel to Succoth, as they were not leaving Egypt. The Israelites were traveling out of Egypt rather than into Succoth, because they were traveling toward the Holy Land. Rashi explains that the fact that the Israelite tribes set out and camped in Succoth only testified that they were traveling toward that country. Tosfot explained that they were traveling from Egypt toward the Promised Land to fulfill the verse "Then I will take you to myself" (15:21), in the event that the Exodus befalls before they have entered the land. And to fulfill the verse "I will set my face toward you" (15:2), they set out from Egypt with their children by their sides. The Torah refers to the Israelites as "the tribe of Levi" in two places, and each time the Torah uses this term it refers to the descendants of Levi, who did not enter the Holy Land. Tosfot explains that "Israel" referred only to those descendants of Levi who did enter the Promised Land, and "the tribe of Levi" referred to those who had entered the Promised Land but did not go to Succoth. B'nai Yosef explain that they were going to Succoth in the hope of being quarantined from the people of Egypt, so that they would not pass on the disease they had contracted, a disease which had rendered them unclean for the next month. The Israelites set out for Succoth en masse. Rather than traveling around Succoth, they traveled through it. This indicates that the

Last Year: The Nightmare free download. Just click the download button on this page to download and install Last Year: The .Q: How to backtrace a closed file I want to trace a process that is "frequently" causing problems, by the file to which its output is redirected becoming "stuck", for me to track down when it opens or closes that file. How can I tell which process

opens or closes a file? A: Well if you are using a terminal to monitor the file, then you can use `lsof | grep /path/to/file` If you're not using a terminal to keep an eye on the file, then you can use `ps`. `cat /proc/pid/cmdline` If you're looking for something in Python, look at `subprocess`.

Nucleic acid hybridization assays are used in many fields of biotechnology to detect, analyze, and isolate nucleic acids of interest. Nucleic acid hybridization is based upon the ability of two nucleic acids having complementary or nearly complementary nucleotide sequences to hybridize to each other. This hybridization event occurs when the two nucleic acids have a sufficient degree of complementarity and when the two nucleic acids have accessible complementary or closely complementary sequences. In general, small and large DNA and RNA fragments are easily hybridized to each other due to the electrostatic attraction and electrostatic repulsion forces that occur between the anionic phosphate groups of one strand to the cationic ammonium groups of the other strand. The affinity of the double helix has been found to increase with a decrease in temperature. Stable hybridization complexes are thus formed in which the complementary bases are held together by a variety of forces such as the hydrogen bonds, van der Waals forces, or ionic bonds formed between adenine, guanine, cytosine, and thymine, as well as other bases. Nucleic acid hybridization is used to detect particular sequences of nucleic acids in a sample by bringing the sample and a probe nucleic acid having a nucleotide sequence complementary to the nucleotide sequence

of the sample nucleic acid under hybridization conditions, usually in a fluid such as water, and detecting complexation that occurs. The detection may be accomplished in many ways, such as by using a label on the probe or on the sample nucleic acid. Examples include radioactive labels and non-
